

# Predictive Analysis for **XYZ's Marketing Campaign**

Ssu Hsien Lee, Alan Chen, Kasturi Pal, Deepanshu Kataria

# Business Problem

## Who is likely to become a premium subscriber?

### Business Model

The company provides a host of basic services for **free** while giving additional **premium features** for an additional monthly **subscription fee**.

### ISSUE

XYZ needs **new subscribers** to take up the monthly subscription plan **to increase revenue**. However, for the next marketing campaign, we don't know **which current non-subscribers** are likely to respond to the marketing campaign and **convert to premium subscribers**.

### Solution

We analyze previous marketing campaign data and **develop a predictive model** to help the executives of XYZ **better predict** which existing users are most likely to take up their subscriptions.

# Business Problem

# Analytics- enabled Marketing Campaign Strategy

**Predictive Model**

Prospective users

subscribers

non-subscribers

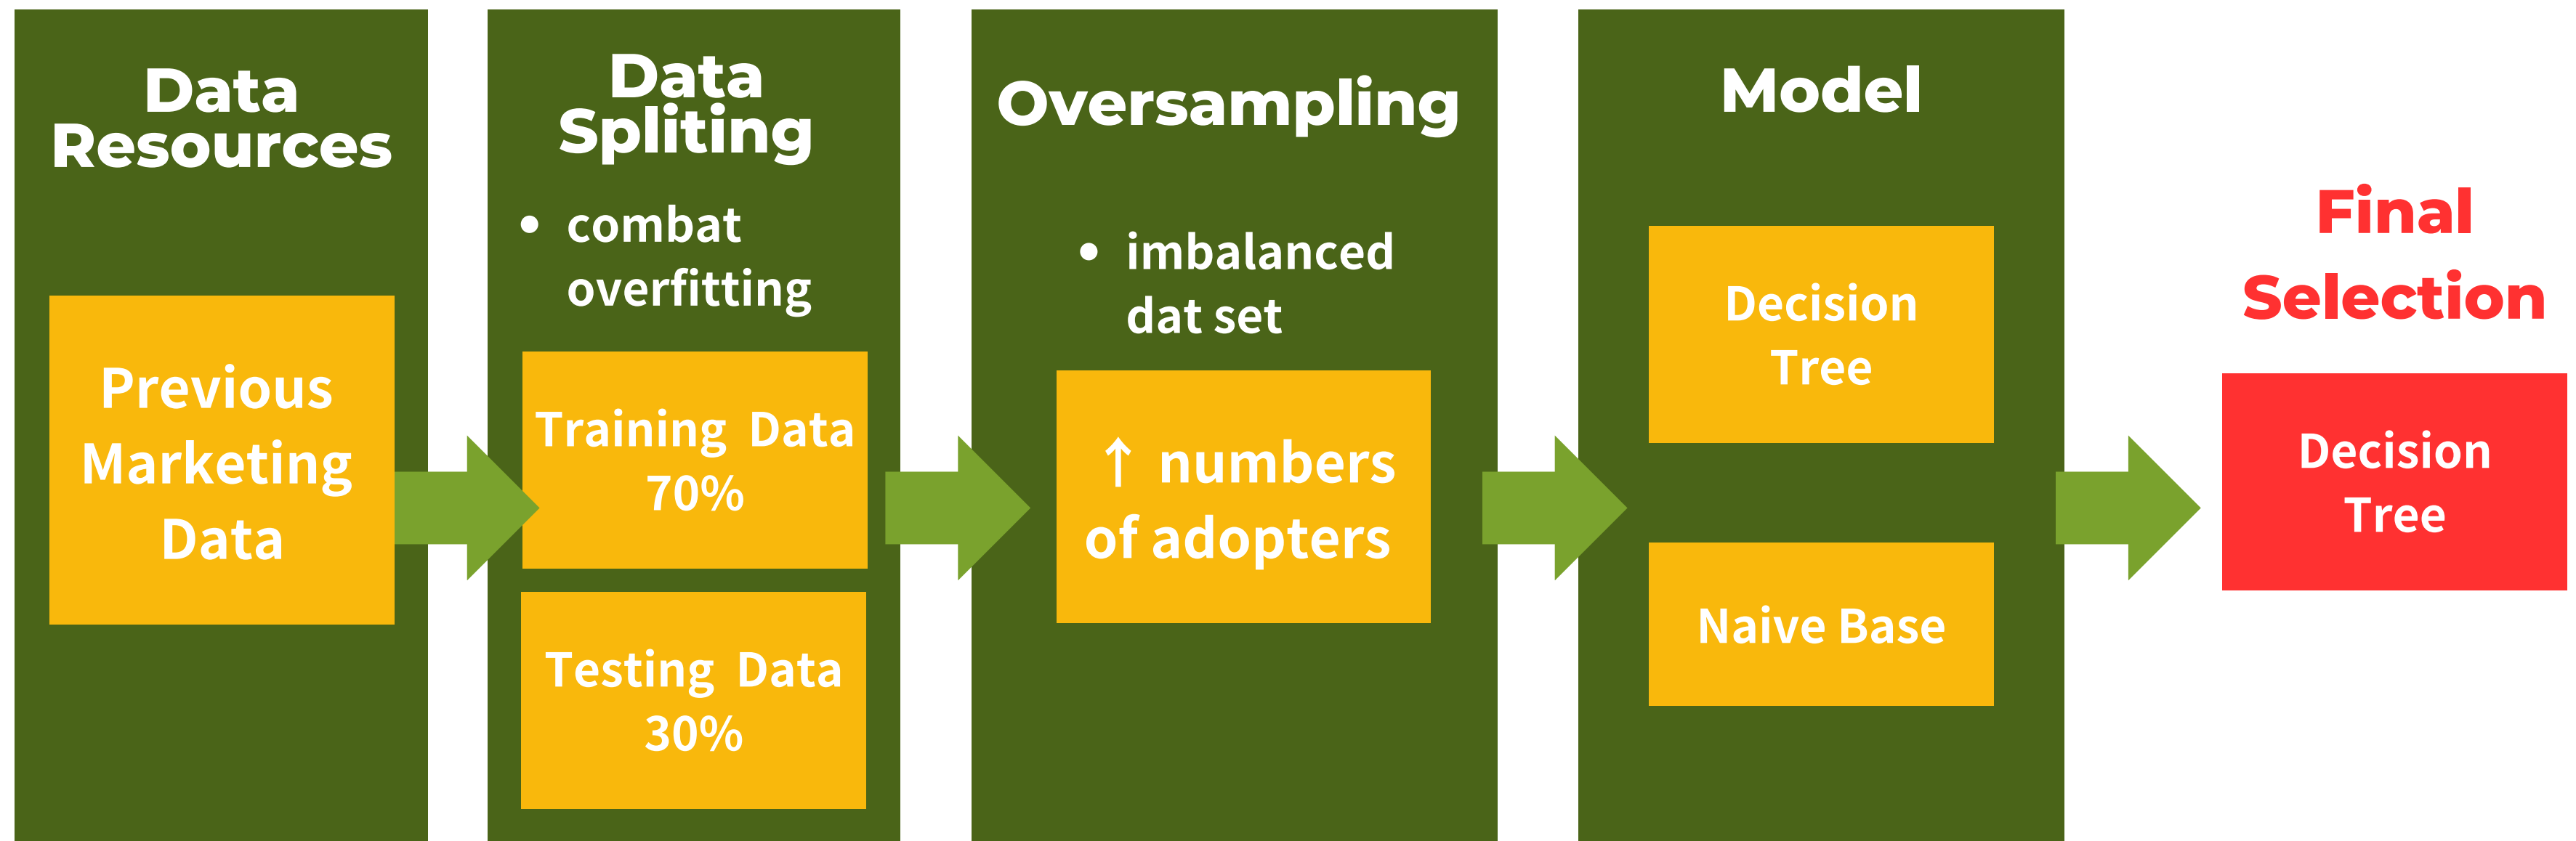

# Data Description

## Overview of Data:

- Total of 41,540 records
- 25 attributes
- Subscribers proportions after previous marketing campaign

# Solution Map - Model Building Process

# How do we know if our model works?

We build different models. However, which model is the best?

**Identify  
evaluation  
performance  
metrics**

**Receiver Operating  
Characteristic (ROC)**

**AUC**

- **scale-invariant**
- **classification-threshold-invariant**

# What does AUC-ROC mean to the problem in context?

The most suitable metric for this marketing campaign analysis

resources: [https://commons.wikimedia.org/wiki/File:Roc\\_curve.svg#filelinks](https://commons.wikimedia.org/wiki/File:Roc_curve.svg#filelinks)

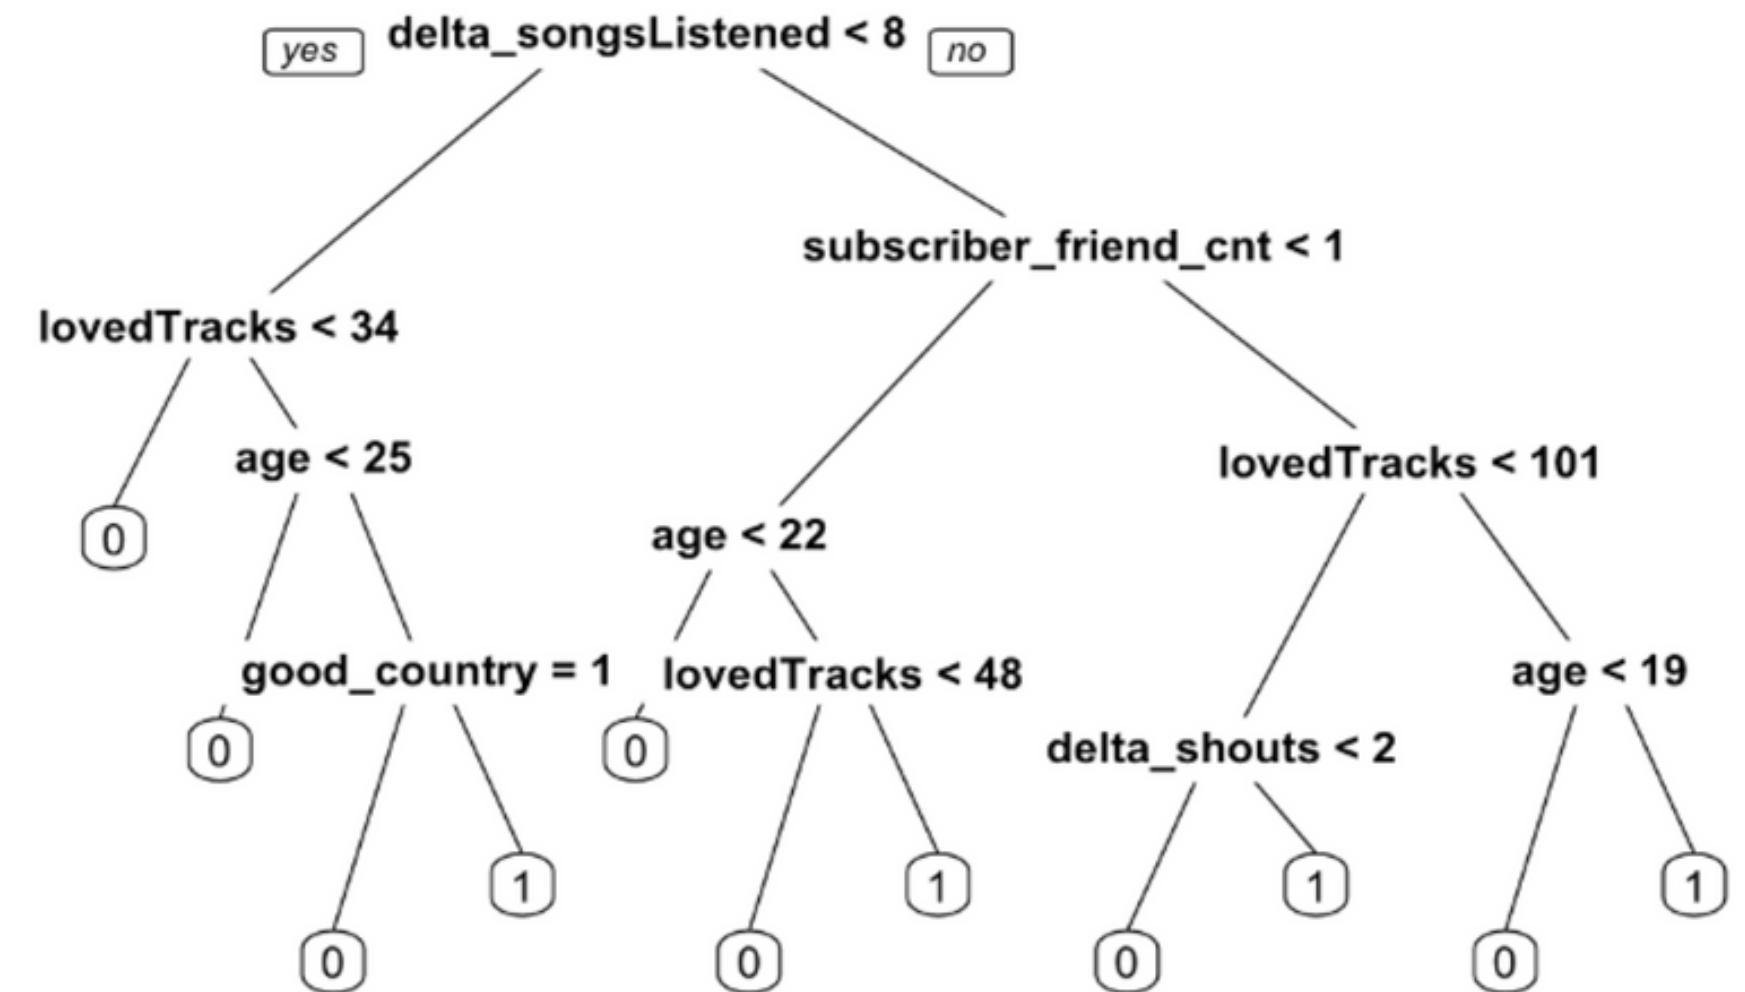

- ROC curve **ranks** the **predictive probabilities** of all the data points.
- AUC is used to **correctly rank the probability** of converting to subscribers ahead of the maintain as free users.
- AUC value should  $> 0.5$  (random model performance)
- AUC is used to predict what percentage of users has a higher predictive probability of being likely to subscribe over the not subscribers records.

# Implication of the Model - Revelant features

## Six most relevant features:

- Delta\_songs\_listened: changes in the number of listening songs
- Subscriber\_friend\_count: number of friends who are subscribers of the premium service
- lovedTracks: total number of different songs that the user "liked"
- Age: ages of users
- delta\_shouts: changes in the number of wall posts received by the user
- good\_country: countries where free usage is more limited, 1 – less limited

# Implication of the Model - 4 Types of users are more likely to sbuscribe

- **Four types** of users are more likely to convert to premium subscribers

Delta\_songs\_listened < 8

age > 25

loved Tracks > 34

Less limited free usage country

Delta\_songs\_listened > 8

Subscriber\_friend\_count < 1

age > 22

loved Tracks > 48

Subscriber\_friend\_count > 1

loved Tracks < 101

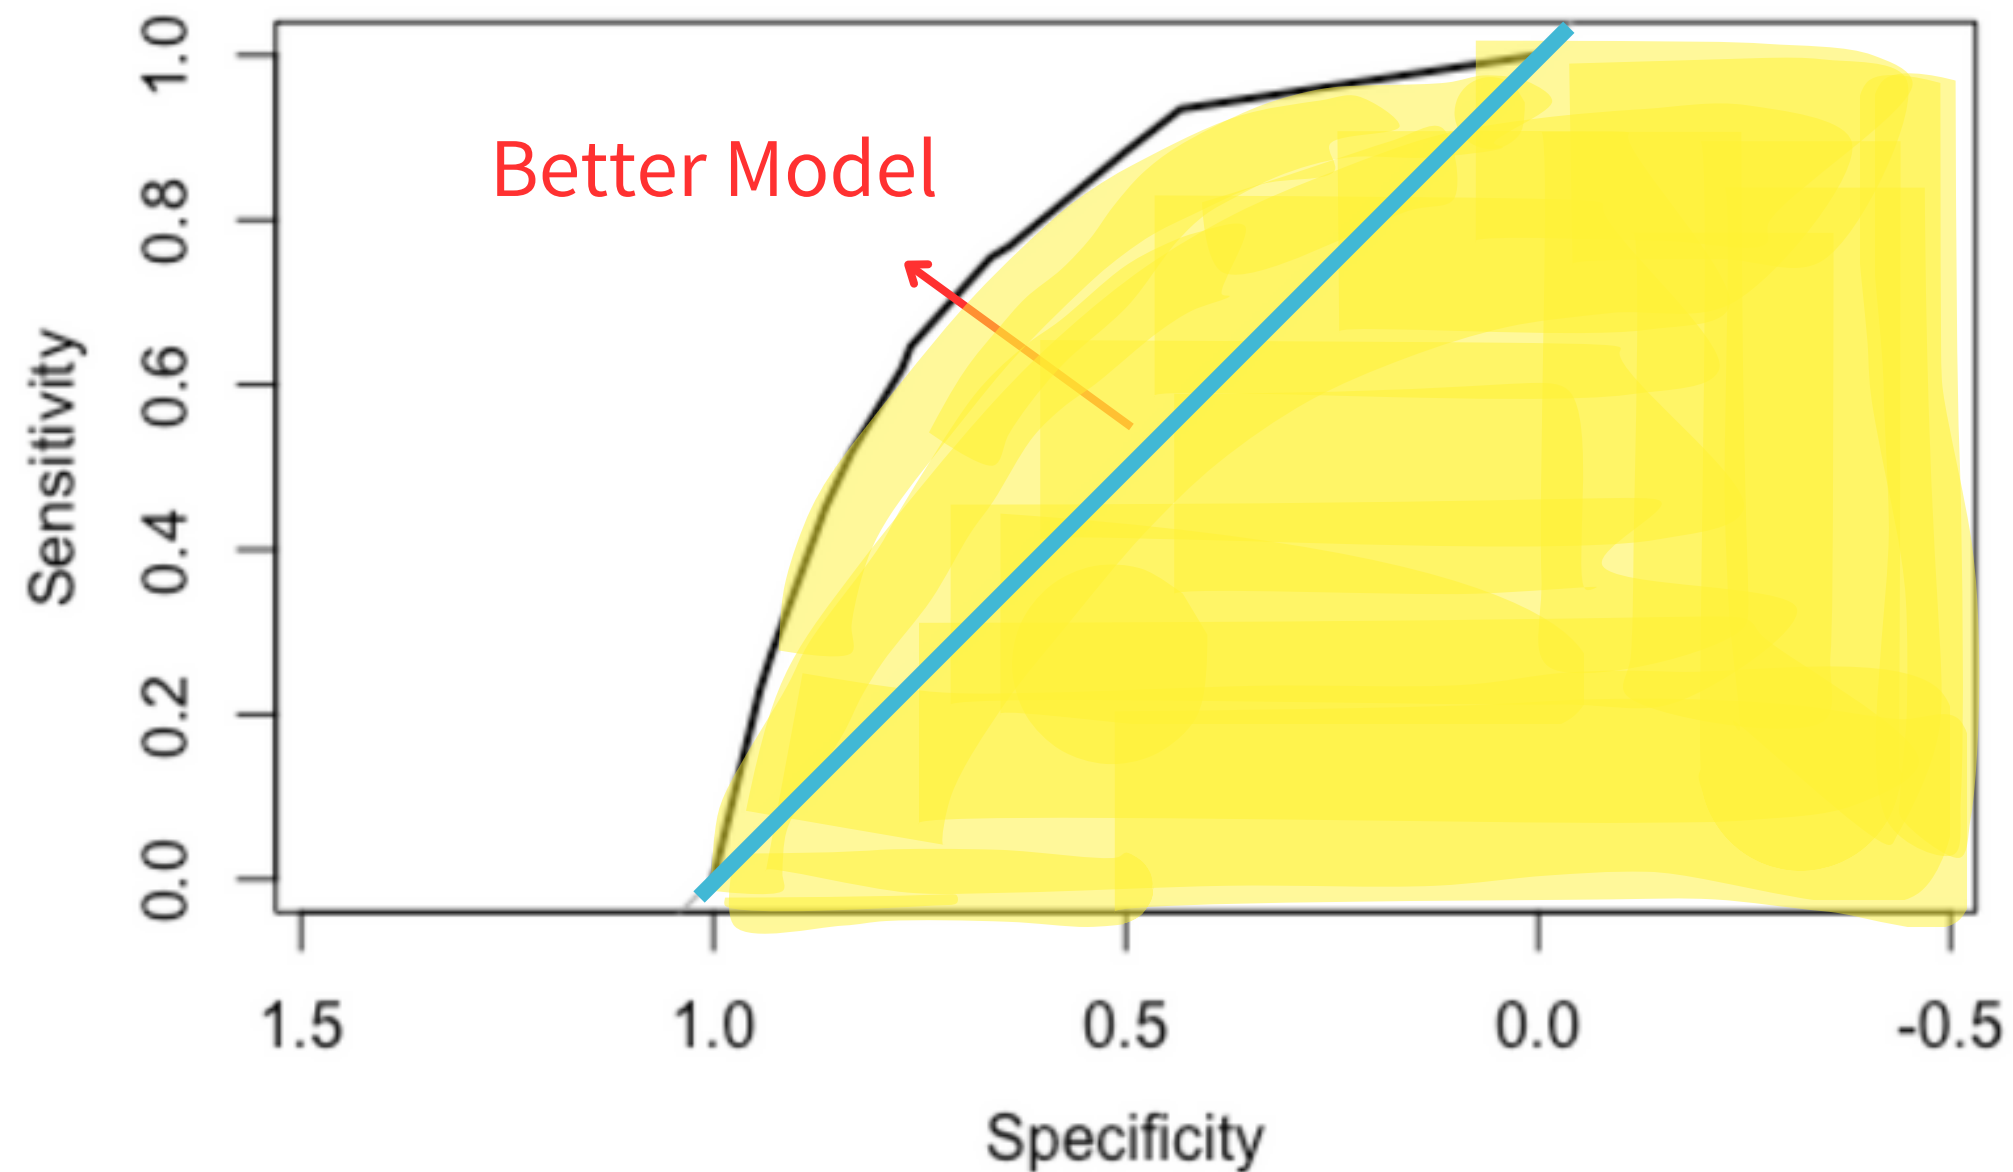

delta\_shouts > 2

age > 19

loved Tracks > 101

# Implication of the Model - Model Performance

	Decision TreeModel	BaseLine Model
AUC	0.77	0.5

The area under this ROC curve, **AUC**, equates to the model' s **ability to predict classes correctly**. As a significant AUC would show that the model can achieve a high true positive rate with a correspondingly low false positive rate.

# Application of the Model

# THANK YOU
